Abstract

Introduction: Following our previous studies on the neuroprotective effects of progesterone and cytokines such as IL-
6 (IL-6) is involved in the inflammatory response, to examine whether changes in IL-6 and Nerve grows factor(NGF)
concentrations in CSF can responsible for the neuroprotective effects of progesterone after traumatic brain injury(TBI).
Materials and Methods: Female ovariectomized rats were divided into 9 groups: intact (pro estrous and non-
proestrous), sham, TBI and 4 groups treated by vehicle or different doses of progesterone, including: vehicle, LP (low
dose of progesterone, 1.7 mg/kg), HP (high dose of progesterone, 8 mg/kg), IVC (implant vehicle capsules, 10-20
ng/ml) and IPC (Implant low dose of progesterone capsules, 10-20 ng/ml). In groups receiving hormone or vehicle,
treatment was administered as a single dose of intraperitoneally 30 minutes or implant capsules 6 hours following a
diffuse TBI that was induced by Marmarou’s method. The levels of biomarkers in CSF were measured at 48 h after the
TBI. Results: Both doses of progesterone reduced CSF levels of IL-6 compared with vehicle group (p<0.05, p<0.001,
respectively), but the difference between CSF levels of NGF in progesterone and vehicle was not significant. After
trauma, although the ratio of NGF to IL-6 significantly higher in the progesterone groups than in the vehicle group
(p<0.05). The CSF level of IL-6 was reduced in IPC group, compared with IVC group (p<0.05), but the CSF level
of NGF is increased (p<0.05). The NGF/IL-6 ratio in IPC group was 4.13 higher following administration of vehicle
(1.16, p<0.001) levels, and the highest maximum NGF/IL-6 ratio is in the same group. Conclusion: Based on our
findings, we conclude that individual measure these two indicators to evaluate the effects of drugs may be not useful,
but CSF NGF/IL-6 ratio might be a better marker for determine the effectiveness of drugs.
