Abstract

Alzheimer disease (AD) is a neurodegenerative disorder marked by cognitive and behavioral impairment. Amyloid beta (A β) peptides are involved in AD as the main component of amyloid plaques found in the brain. Recent in vivo and in vitro studies have shown that there is a lot of substances that alter A β pathogenesis of AD. A β induces toxicity lead to increasing ROS. In the other hand, 5-HT₆ and Aloe arborescence recently reported to protect cells from this effect. Additionally, A β oligomers interact with neurons through Nrx2a and NL1 receptors by blocking these receptors; one can reduce the A β -induced memory impairment. Moreover, A β aggregation correlates with high concentration of Fe (III) and Cu (II). And chelators decreased significantly aggregation of A β in synaptic cleft. By knowing the mechanism of A β toxicity, new therapeutic approaches can be developed to prevent AD or alleviate disability caused by it. JC-124 treatment leads to decrease levels of A β deposition. Bosentan, a dual endothelin receptor antagonist, offers protection against A β -induced endothelial damage. Anti Nrx2a and NL1 reduces A β -induced memory impairment in mice. Clitaquinol inhibits disaggregation of A β at low pHs. In this article we review the substances that have a role in the toxicity of A β and can be considered as a new target for the management of AD.
