#### Abstract

Neuronal nitric oxide synthase (nNOS) plays a role in synaptic potentiation and kindling process. The relationship between nNOS and 5-HT<sub>1A</sub> receptors also nearly has been specified. In this research, we investigate the role of nNOS on the anticonvulsant effect of 5-HT<sub>1A</sub> receptors. 24 male (280 ± 30 g) were randomly assigned to four groups (vehicle, NI, Way 100635 and NI + Way100635) (n = 6). Animals received one of the above compounds 30 min before application of the kindling stimulus. In the NI + Way100635 group, 10 min later Intra ventricle injection Way100635, intraperitoneal nitroindazole (NI) was injected. After application daily stimulation (12 times a day, with a 5 minute interval), up to five days, the seizure and electrophysiological quantities (after discharge duration and local field potentials) were recorded and measured. Data analysis showed that the Way100635 and NI+Way groups were kindled significantly faster than the vehicle group (P < 0.001). The changes in afterdischarge duration increased in the NI + Way group over the five days when compared to the control group, but was not significant (P > 0.05). Also, the slope of field potentials in the NI + Way group was significantly higher than that of the vehicle group (P < 0.05). Likely, nNOS is one of the mediators of the inhibitory effect of serotonin 5-HT<sub>1A</sub> receptors, and activating this pathway augments the anticonvulsant effects of serotonin.
